LE

Dear all,

in this mail I want to share some information about the lab project with you. We will be working on rapeseed plant feeding-damage quantification. This is actually part of a project trying to find resistant plants against pests, so your work will really have an impact and might be applied in a real scenario!

More information is attached. You will find both my own slides for the project as well as some information that I got from the project partners. You can already look at the information and start working on it. Let's meet next Tuesday at 4pm to discuss further questions.

The data is uploaded

under [/home/nfs/data/nvme_datasets/Pictures_CFSB_leaf_damage](#), please check if you can access it.

I first want every team to implement a baseline approach, which consists of a classical finetuning objective. We will use DinoV3 for the baseline. Then, there are further improvements ("directions") that are possible to try out. Every team should choose one that they want to focus on first and we will see what works well. Note that Domain-Adaptation might be very compute-heavy.

So if you haven't already, I would recommend you to apply to get compute resources at Bender. If they denied you or didn't respond, please write me, and I will contact them myself.

Kind regards,
Luca Eichler
